

Entity-deduplicated as-of view — bitemporal slice, survivorship merge, then a deficiency-gated publish

Read any point in time, at entity grain. The bitemporal slice fixes both clocks — valid time (*scd2*, the business fact) and system time (*sys*, when we knew it) — so you see the data as it was believed at t_s about the world at t_v , including later corrections made to historical facts. **Survivorship** then dedups the sliced rows to real-world entities: many source records collapse to ONE golden record, each attribute taken from the surviving source (*metadata* can carry the trust / priority / recency the merge uses).

Publishing is gated. Any as-of view must pass the same deficiency test that drives rule curation. Some (t_v, t_s) points still **fail** — they carry unresolved deficiencies — and are **not publishable** until curated rules (merged to git main) resolve them. As corrections land over system time, more of the plane becomes publishable.
